## FOREWORD

The vast majority of sea ice data in the world today is stored in the form of ice charts prepared by the various ice services of different countries. It has long been recognized that data in this form have limited use for statistical and climatological summaries. Efforts are now being made by several countries to construct digital representations of these charts.

The United States Navy/National Oceanic and Atmospheric Administration (NOAA) Joint Ice Center (JIC) initiated a Sea Ice Digitization Program funded by the United States Navy in 1981. This Atlas and its Arctic West and Antarctic counterparts are a result of that initiative. Having ice data in digital format allows the construction of composite analyses that previously would have been impractical to produce.

## ACKNOWLEDGEMENTS

This Atlas was prepared under the auspices of the Commander, Naval Oceanography Command and was coordinated by the Naval Oceanography Command Detachment, Asheville, North Carolina. The work was performed by the National Climatic Data Center (NCDC) in Asheville, North Carolina.

Specific acknowledgement is made to members of NCDC: Project Manager and System Designer, Richard Knight; and digitizer technicians Elizabeth Koon and Carmen Gray. Credit is given to Mr. Raymond H. Godin, Lieutenant Commander Bradley P. Smith, USN, and Mr. Don G. Barnett of the Joint Ice Center/Naval Polar Oceanography Center for their considerable efforts involving the analysis of the final summaries and quality control of the charts. Also credited are Lieutenant Commander A. K. Trapp, Lieutenant Commander D. Butler and Brian Wallace of the Naval Oceanography Command Detachment, Asheville for their help in coordinating the project.

## INTRODUCTION

Through 1965, reliable sea ice information in the Arctic regions was based on limited aerial reconnaissance data augmented by sparse shore station and ship reports. These data were further restricted to relatively small areas observed primarily during the summer season. From 1966 to 1972, the addition of visible and infrared satellite imagery expanded analysis capabilities, but considerable limitations were still imposed by clouds and seasonal darkness. Since the further addition in 1973 of all weather/season passive microwave satellite imagery, it has been possible to routinely map the extent of Arctic sea ice on a global scale. Arctic sea ice analyses have been operationally produced on a weekly basis since January 1973. This atlas contains sea ice summaries derived from 574 weekly JIC sea ice analyses produced from 1972 through 1982.

# OVERVIEW

## I. DATA SOURCES

The weekly analyses (Figure 1) produced at the JIC result from the synthesis of four general groups of data. These data sources are: 1) shore station reports, 2) ship reports, 3) aerial reconnaissance, and 4) satellite imagery and data. Satellite imagery and data, however, comprises over 90 percent of the data utilized in the Arctic sea ice analyses.

The satellite data utilized fall into three categories: 1) visible imagery, 2) thermal infrared imagery, and 3) passive microwave imagery and data. Visible and infrared imagery have been utilized from a series of NOAA Polar Orbiting Satellites and Defense Meteorological Satellite Program (DMSP) satellites. Passive microwave imagery have been utilized from the NIMBUS-5 Electrically Scanning Microwave Radiometer (ESMR) and the NIMBUS-7 Scanning Multichannel Microwave Radiometer (SMMR). A near continuous source of passive microwave imagery and data has been available since January 1973. Table 1 identifies satellite sensors utilized from 1979 through 1982. Accurate records of satellite data used at the JIC prior to 1979 are not available. Estimates have been made concerning the percent of utilization of each of the satellite sources. During the summer, visible and infrared imagery provides about 65% of the data and passive microwave 35%. During the winter, the figures are approximately 35% and 65% respectively.

## II. DIGITIZATION

Each weekly sea ice analysis chart has been digitized at the NCDC. This process converts the analog data to digital values at predetermined grid points. The digital data are stored in a standardized format called SIGRID (Sea Ice GRID) which is under study for adoption by the World Meteorological Organization. The grid points are identified by earth coordinates and have a resolution of 15 nautical miles or better.

## III. COMPOSITING TECHNIQUE

The SIGRID format is easily expanded to provide ice data at each grid point over the Polar region. One can think of each grid point as being a cell in a two dimensional matrix. In a composite analysis, each cell becomes a storage location for accumulating some derived quantity of interest. For example, if we are given a ten-chart period of record, we could count the number of times that ice was observed in the grid cell located at say: 75N, 179W. If the composite count were eight (8) we could then say that there was an 80 percent probability of occurrence of ice at 75N, 179W for that period of record. In a similar fashion, other quantities such as sea ice concentration may be accumulated in a gridded array and subsequently used in a composite analysis.

## IV. CALCULATIONS

This atlas contains groups of charts composited over a semi-monthly period centered on the first (1st) and the fifteenth (15th) of each month. The composite classifications are as follows:

- 1) Maximum, Mean and Minimum Ice Edges
- 2) Probability of Occurrence of Any Ice
- 3) Mean Ice Concentration
- 4) Mean Ice Concentration When Ice is Present
- 5) Maximum, Mean and Minimum Extent of 5/10ths or More of Ice

Each composite classification contains three or more boundary categories. The isopleth that defines each boundary is determined by the existence of a particular composite grid cell value. The grid cells that meet the specified boundary criterion are identified and re-labeled with a single digit. Thus, for example, all of the grid cells meeting the boundary criterion for minimum sea ice edge would be identified with a code digit '3'. In general, there are hundreds, sometimes

## MAXIMUM, MEAN AND MINIMUM ICE EDGE

Composite values, V, within a given grid cell are defined as:

$$V = \sum_{i=1}^N Z_i$$

Z is a binary value defined as:  
 0 - non-occurrence of ice  
 1 - occurrence of ice

N is the number of charts used in the compositing period.

The three ice edges are defined as:

Maximum Ice Edge -  $V \geq 1$   
 Mean Ice Edge -  $V \geq .5N$   
 Minimum Ice Edge -  $V = N$

## PROBABILITY OF OCCURRENCE OF ANY ICE

$$V = \sum_{i=1}^N Z_i$$

Z is a binary value defined as:  
 0 - non-occurrence of ice  
 1 - occurrence of ice

N is the number of charts

The five isopleths are defined as:

Greater than 0% Probability  $V \geq 1$   
 20% Probability  $V \geq .2N$   
 40% Probability  $V \geq .4N$   
 60% Probability  $V \geq .6N$   
 80% Probability  $V \geq .8N$

## MEAN ICE CONCENTRATION

$$V = \frac{\sum_{i=1}^N C_i}{N}$$

C is the ice concentration in percent

N is the number of charts

The four isopleths are defined as:

Greater than 0% Concentration  $V > 0$   
 20% Concentration  $V \geq 20$   
 50% Concentration  $V \geq 50$   
 80% Concentration  $V \geq 80$

## MEAN ICE CONCENTRATION WHEN ICE IS PRESENT

The definition is identical to Mean Ice Concentration except that N represents the number of charts having an ice concentration greater than zero in the selected grid cell. This prevents the mean ice concentration from being diluted by periods of no ice.

## MAXIMUM, MEAN AND MINIMUM EXTENT

Satellite imagery and data, however, comprises over 90 percent of the data utilized in the Arctic sea ice analyses.

The satellite data utilized fall into three categories: 1) visible imagery, 2) thermal infrared imagery, and 3) passive microwave imagery and data. Visible and infrared imagery have been utilized from a series of NOAA Polar Orbiting Satellites and Defense Meteorological Satellite Program (DMSP) satellites. Passive microwave imagery have been utilized from the NIMBUS-5 Electrically Scanning Microwave Radiometer (ESMR) and the NIMBUS-7 Scanning Multichannel Microwave Radiometer (SMMR). A near continuous source of passive microwave imagery and data has been available since January 1973. Table 1 identifies satellite sensors utilized from 1979 through 1982. Accurate records of satellite data used at the JIC prior to 1979 are not available. Estimates have been made concerning the percent of utilization of each of the satellite sources. During the summer, visible and infrared imagery provides about 65% of the data and passive microwave 35%. During the winter, the figures are approximately 35% and 65% respectively.

## II. DIGITIZATION

Each weekly sea ice analysis chart has been digitized at the NCDC. This process converts the analog data to digital values at predetermined grid points. The digital data are stored in a standardized format called SIGRID (Sea Ice GRID) which is under study for adoption by the World Meteorological Organization. The grid points are identified by earth coordinates and have a resolution of 15 nautical miles or better.

## III. COMPOSITING TECHNIQUE

The SIGRID format is easily expanded to provide ice data at each grid point over the Polar region. One can think of each grid point as being a cell in a two dimensional matrix. In a composite analysis, each cell becomes a storage location for accumulating some derived quantity of interest. For example, if we are given a ten-chart period of record, we could count the number of times that ice was observed in the grid cell located at say: 75N, 179W. If the composite count were eight (8) we could then say that there was an 80 percent probability of occurrence of ice at 75N, 179W for that period of record. In a similar fashion, other quantities such as sea ice concentration may be accumulated in a gridded array and subsequently used in a composite analysis.

## IV. CALCULATIONS

This atlas contains groups of charts composited over a semi-monthly period centered on the first (1st) and the fifteenth (15th) of each month. The composite classifications are as follows:

- 1) Maximum, Mean and Minimum Ice Edges
- 2) Probability of Occurrence of Any Ice
- 3) Mean Ice Concentration
- 4) Mean Ice Concentration When Ice is Present
- 5) Maximum, Mean and Minimum Extent of 5/10ths or More of Ice

Each composite classification contains three or more boundary categories. The isopleth that defines each boundary is determined by the existence of a particular composite grid cell value. The grid cells that meet the specified boundary criterion are identified and re-labeled with a single digit. Thus, for example, all of the grid cells meeting the boundary criterion for minimum sea ice edge would be identified with a code digit '3'. In general, there are hundreds, sometimes thousands, of adjacent grid cells sharing the same identification code digit. To find the peripheral boundary of this example region one can eliminate, in a graphical sense, all of the false partitions that exist between cells containing the same identification code. What is left is the boundary separating grid cells meeting one criterion from grid cells meeting different criteria. Clearly, one could envision certain situations where this method of boundary analysis would yield rather chaotic results. However, thanks to the inherent continuity or persistence of sea ice features this method works quite well. The boundary criteria utilized in the various ice climatology classifications are as follows.

N is the number of charts used in the compositing period.

The three ice edges are defined as:

Maximum Ice Edge -  $V \geq 1$   
 Mean Ice Edge -  $V \geq .5N$   
 Minimum Ice Edge -  $V = N$

## PROBABILITY OF OCCURRENCE OF ANY ICE

Z is a binary value defined as:  
 0 - non-occurrence of ice  
 1 - occurrence of ice

$$V = \sum_{i=1}^N Z_i$$

N is the number of charts

The five isopleths are defined as:

Greater than 0% Probability  $V \geq 1$   
 20% Probability  $V \geq .2N$   
 40% Probability  $V \geq .4N$   
 60% Probability  $V \geq .6N$   
 80% Probability  $V \geq .8N$

## MEAN ICE CONCENTRATION

$$V = \frac{\sum_{i=1}^N C_i}{N}$$

C is the ice concentration in percent

N is the number of charts

The four isopleths are defined as:

Greater than 0% Concentration  $V > 0$   
 20% Concentration  $V \geq 20$   
 50% Concentration  $V \geq 50$   
 80% Concentration  $V \geq 80$

## MEAN ICE CONCENTRATION WHEN ICE IS PRESENT

The definition is identical to Mean Ice Concentration except that N represents the number of charts having an ice concentration greater than zero in the selected grid cell. This prevents the mean ice concentration from being diluted by periods of no ice.

## MAXIMUM, MEAN AND MINIMUM EXTENT OF 5/10ths OR MORE OF ICE

The definition is the same as for Maximum, Mean and Minimum Ice Edge with the exception of the definition of Z which is now:

Z is a binary value defined as:  
 0 - non-occurrence of 5/10ths or more of ice  
 1 - occurrence of 5/10ths or more of ice.

## V. INTERPRETATION

Interpretation of the charts in this Atlas should be straightforward. A possible conflict may arise if one tries to reconcile the terminology "ice edge" with the depiction of the shaded area. The shaded presentation was chosen in lieu of simpler isopleth display to minimize the chance for false interpretation of the data. This is because a label on an isopleth does not explicitly define the conditions on either side of the line. The slope of the gradient is not so clearly obvious as it is on a topographic map of the Earth's surface. This is compounded by the fact that the presence of sea ice is *discontinuous* in nature and whereby regions of 80% mean ice concentrations may be bordering regions of 20% ice concentrations with no intermediate region of 50% ice concentration. Shading provides an unequivocal sense of direction to the slope of the gradient which is quite necessary for correct interpretation, especially during the spring and summer seasons.

An alternate way of thinking about the meaning of a particular shaded area is to refer directly to the definitions given above. Using these, one can interpret the shaded areas for Minimum Ice Edge as being an aggregation of grid cells which always contained ice over the composite period. The shaded area that falls between the Mean Ice Edge and the Minimum Ice Edge are all those cells that contained ice at least half of the composite period. Likewise, the shaded area between the Mean Ice Edge and the Maximum Ice Edge represents all those cells that contained ice at least once in the composite period but not more than half of the composite period. Interpretations of the other shading classifications can be made in a similar manner.

Experience has shown that when sea ice occurs in a particular area it almost always occurs in high concentrations. For this reason the Mean Ice Concentration When Ice is Present summary was developed. Because the Mean Ice Concentration summary treats instances of no ice occurrence as zero ice concentration the summary may present misleadingly low concentration values as compared with the ice concentrations actually encountered. Figures 2, 3 and 4 illustrate a case in point. A vessel planning on penetrating the ice pack to the Antarctic continent along the route indicated would expect to encounter ice of 0 tenths to 2 tenths concentration based on the Mean Ice Concentration, Figure 2. Examining the Probability of Occurrence of Any Ice, Figure 3, and the Mean Ice Concentration When Ice is Present, Figure 4, it is apparent that there is a 0% to 20% probability of encountering ice but that if encountered, it will be 2 tenths to 6 tenths concentration. For ships that are not icebreakers but are merely ice reinforced or not reinforced at all the difference in expected ice concentration may make a significant difference in the planning and the eventual outcome of the voyage.

## TABLE AND FIGURES

Two ice-coverage statistics are presented. The first is the summation of ice coverage is the summation of ice. The total ice coverage is multiplied by the concentration to give an equivalent area of 100% concentration.

Total extent and coverage (90°W - 90°E) as well as for the fourteen tables contain data for a set of fourteen tables is semi-fifteenth of each month.

Following the tables there are ice coverage and extent for the years 1972-1982.

## FIGURES OF ICE COVERAGE AND EXTENT

Statistics are presented in tabular form. The total extent of areas of all grid cells having any concentration of ice category is the summation of the area in each grid cell in that cell. Thus, total coverage is a measure of concentration of ice.

Statistics are presented for the entire Arctic East or thirteen sub areas (see Figure below). The first is for each weekly chart that was digitized. The second is semi-monthly composite data centered on the first and

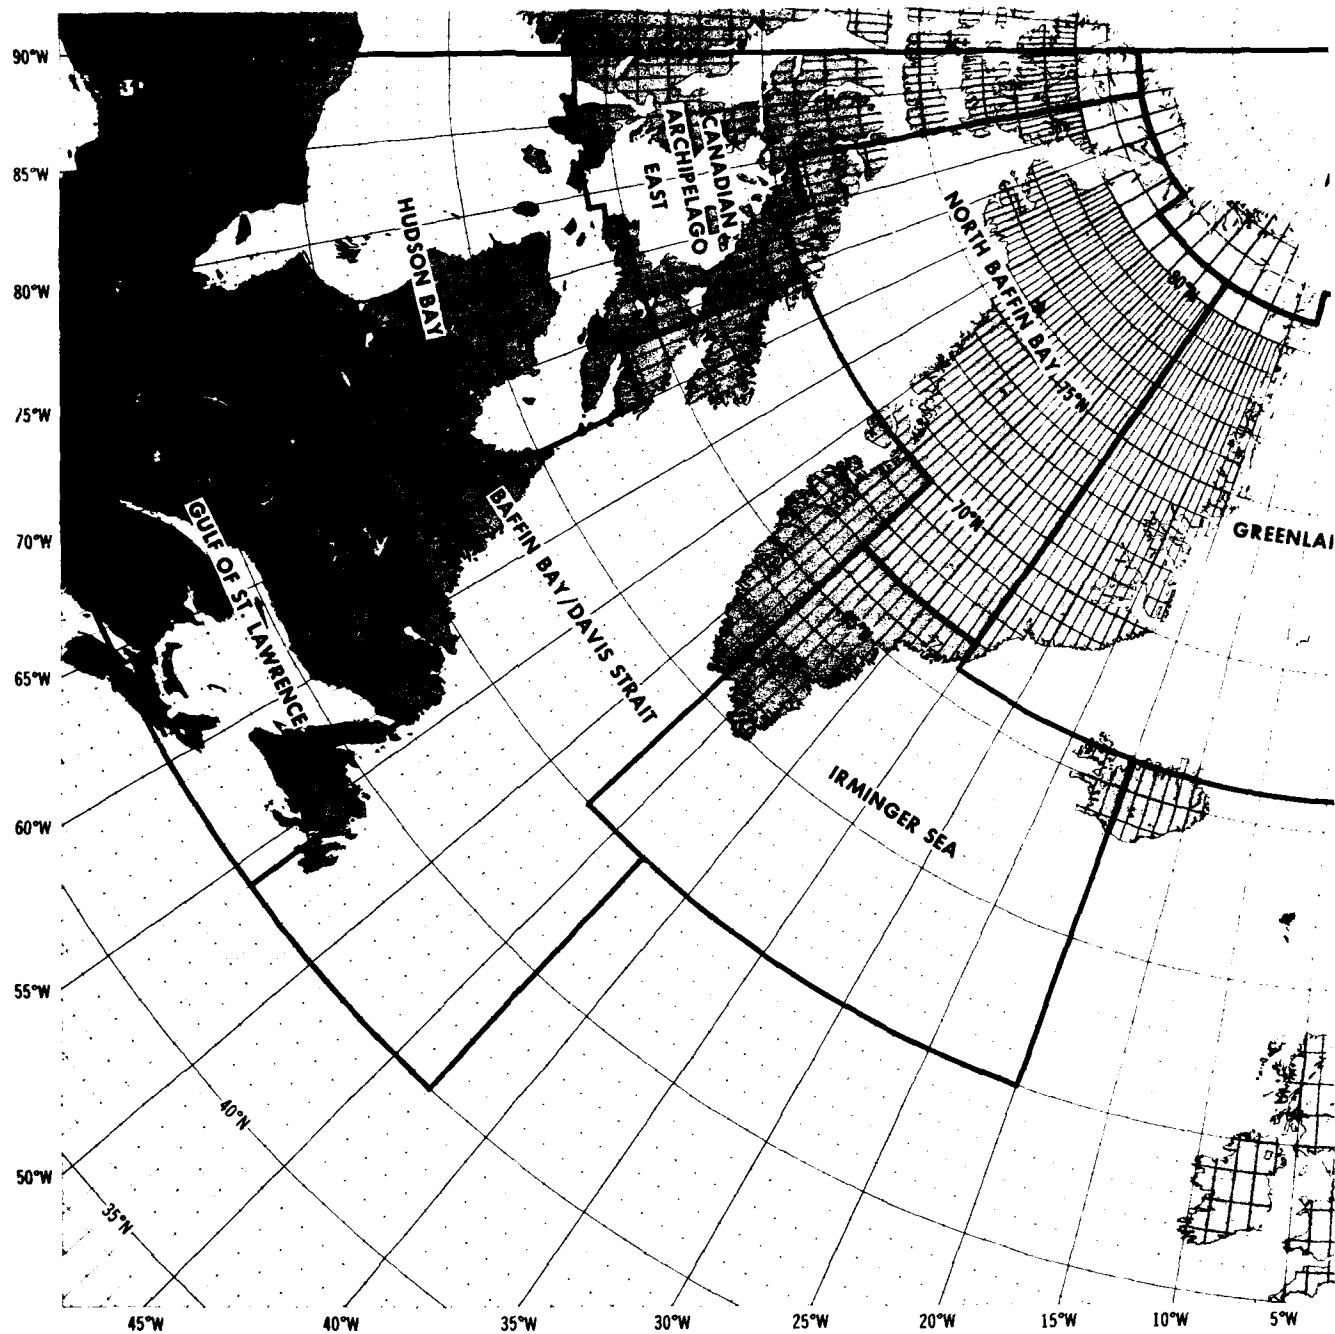

there are fourteen figures showing the time-series of total for the entire Arctic East and each of the thirteen sub areas

Two ice-coverage statistics: ice coverage is the summation of ice. The total ice coverage calculated by the concentration multiplied by the concentration an equivalent area of 100% concentration.

Total extent and coverage (90°W - 90°E) as well as for the fourteen tables contain data for set of fourteen tables is semi-fifteenth of each month.

Following the tables there ice coverage and extent for the for the years 1972-1982.

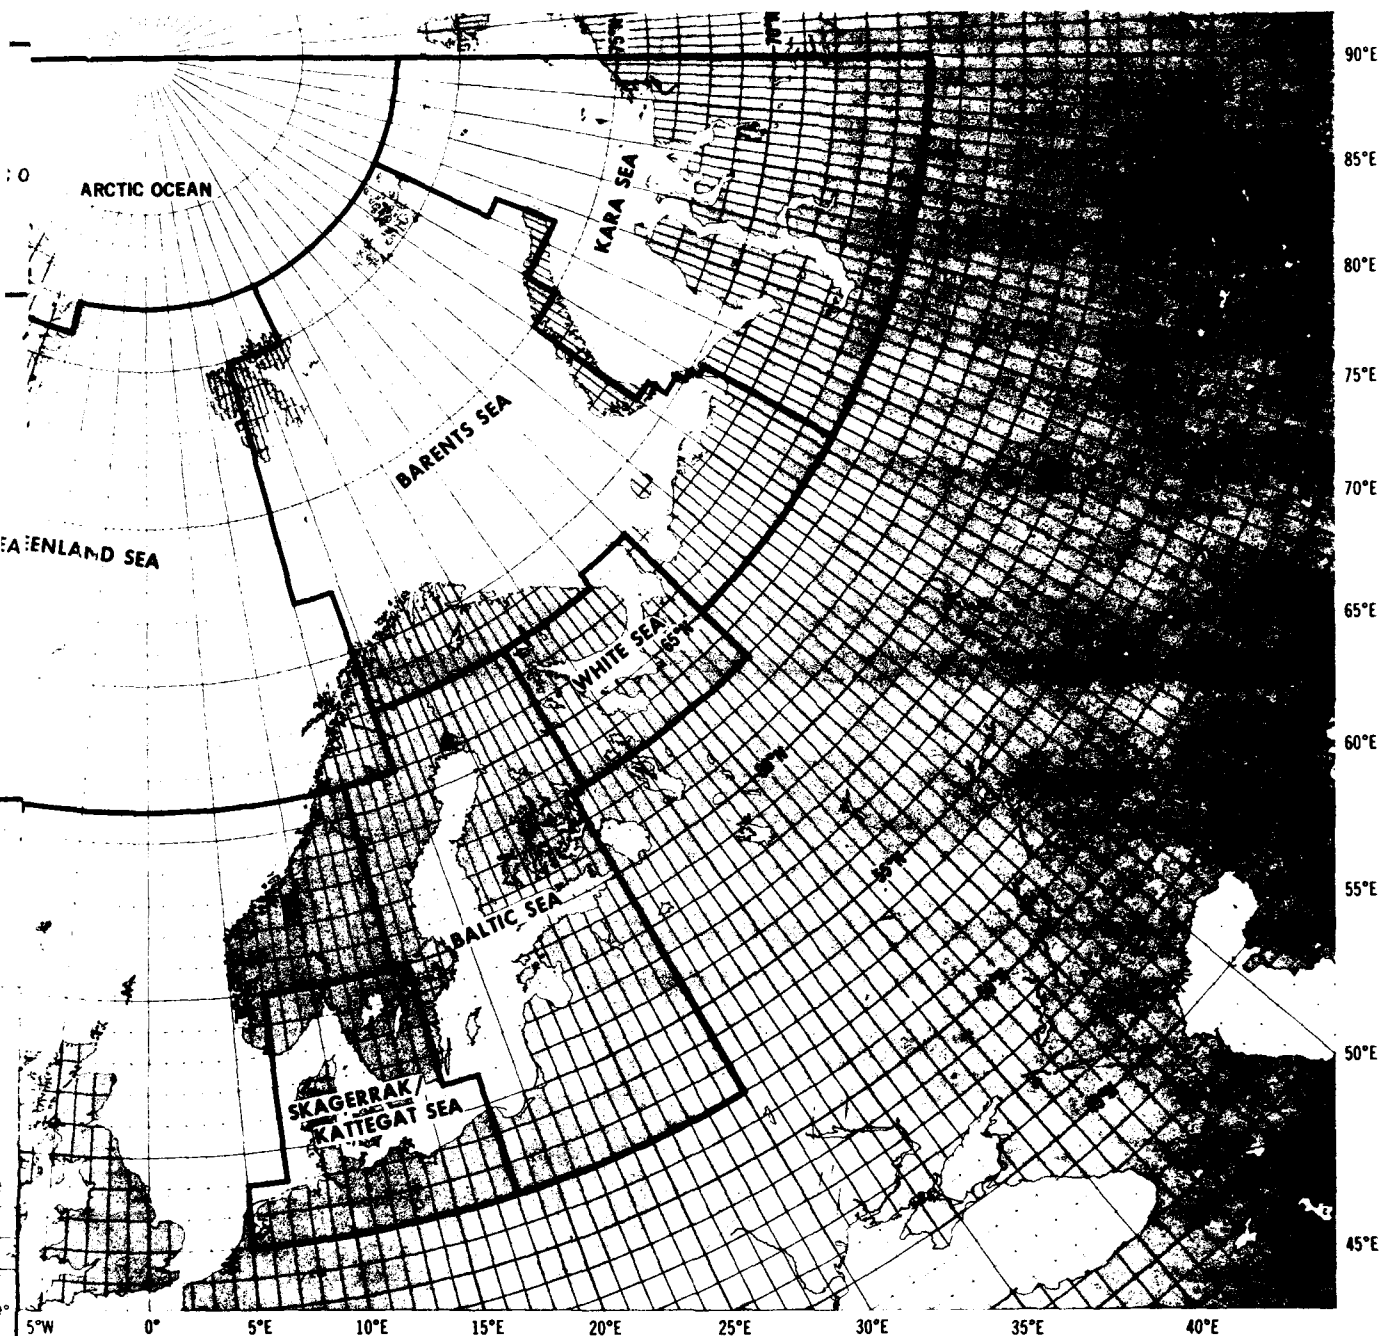

Statistics are presented in tabular form. The total extent of  
on of areas of all grid cells having any concentration of  
e category is the summation of the area in each grid cell  
tion in that cell. Thus, total coverage is a measure of  
concentration of ice.

Age statistics are presented for the entire Arctic East  
r thirteen sub areas (see Figure below). The first  
a for each weekly chart that was digitized. The second  
semi-monthly composite data centered on the first and

There are fourteen figures showing the time-series of total  
the entire Arctic East and each of the thirteen sub areas
